Abstract
Recurrent ingestion of sharp foreign body ingestion is a rare phenomenon but it challenges the surgeon since the patient often has been operated on several times before, making a simple gastrotomy a high risk procedure. Here we report a patient with 23 prior procedures due to foreign body ingestion of which 15 were knives. In the case presented she had an 18 cm long steak knife embedded in the esophageal mucosa. An overtube was not available why a rigid endoscope was successfully used in combination with a colon polypectomy snare.

Introduction
Foreign body ingestion (FBI) is often accidental ingestion of teeth, dentures, plastic, fish- or chicken bones in the elderly population (>65 years) [1]. However, in a study of Palta et al they investigated an adult population with a mean age of 45 years and found that 92% of the cases were intentional. Eightyfive percent suffered from a psychiatric disease and 84% were recurrent cases [2]. Zamary, et al included 1,164 patients with gastrointestinal FBI in a retrospective study. Of these, 169 were sharp foreign bodies. The study concluded, that upper gastric sharp foreign bodies should be removed endoscopically when possible, and the size of the ingested object correlated with the need of a surgical approach [3].

Intentional FBI is a rare phenomenon, but cases are usually observed in inmates, substance abusers and mentally ill patients [4,5]. Recurring incidences complicate surgery due to increased risk of formation of adherences and ileus. Palta et al. reported 262 cases of gastric foreign body ingestion with a success rate of 90% with endoscopic extraction and a need for surgical intervention in 11% of the cases [2].

Here we report an extreme case of a 25-year old woman with 25 prior admissions (23 procedures) due to intentional ingestion of foreign bodies, of which 14 were knives or other sharp instruments. An explorative laparotomy would have been a high risk procedure due to numerous previous surgeries. An overtube was not available and therefore as a last resort the knife was removed with a rigid endoscope and a colon polypectomy wire snare.

Case Presentation
A 25-year old woman was admitted to our institution due to ingestion of a 18 cm long knife 2-4 hours previously (Figure 1). She had a history of paranoid schizophrenia, borderline personality disorder and an unspecified eating disorder. Over the past four years she had been admitted 25 times due to ingestion of foreign bodies in attempts of suicide. Of these, 11 incidences were ingestion of knives (Figure 2). She had undergone 16 endoscopies and 12 laparotomies (six conversions from endoscopy to laparotomy). Besides this her medical history was trivial.

On admission she was stable and x-ray showed an 18 cm steak knife located in the upper half of her esophagus with the wooden shaft leading (Figure 1). Due to 12 previous laparotomies it was decided she was not a good candidate for laparotomy and several attempts to remove the knife with a flexible endoscope were made. However, the tip of the knife was embedded in the esophageal mucosa, just below the upper esophageal sphincter, which further complicated mobilization of the knife. Finally, a rigid endoscope was introduced operated by an ear-nose-throat specialist. The tip of the rigid scope was retracted on the tip of the knife and pressed down by which the tip of the knife slipped out of the mucosa and was captured by the rim of the rigid scope. A colon polypectomy wire snare was introduced through the rigid endoscope and placed around the tip of the knife (Figure 3). The knife could then safely be extracted with the tip embedded in the rim of the rigid scope.

**Discussion**

Cases of intentional sharp FBIs are uncommon and are often patients suffer from mental illness or are inmates with a wish to be transferred to a hospital facility [1,2,6]. So far, our case has 29 admissions due to intentional foreign body ingestions, of which 15 were sharp objects (the incident described being nr. 26).

Use of a colon polypectomy wire snare to remove foreign bodies in the upper gastrointestinal canal has been described earlier and has a high success rate, also with larger objects [2]. It can provide a very strong traction force, but for objects embedded in mucosa, correct placement of the sling can be extremely difficult. Applying a colon polypectomy wire snare through the working channel of a flexible endoscope in the area just below the upper esophageal sphincter is challenging because of loss of vision and the space needed to open the snare. At our institution rigid endoscopy of the esophagus has been
